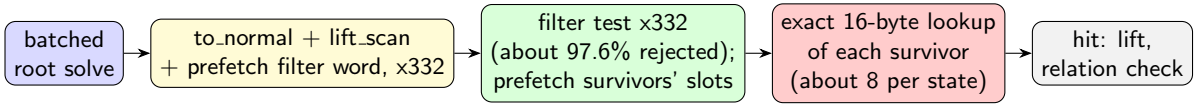
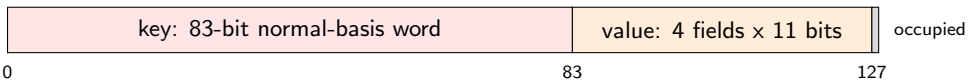
One index state, about 332 partner probes, in the pipeline's order



Filter: 2^{22} words of 64 bits (32 MiB, 16 huge pages), 5 bits per key in one word

word = top 22 bits of h(key); bits = five 6-bit groups of h's low 30 bits; hit iff all five set

Slot: one 128-bit word, 2^{27} slots (2 GiB), same hash and linear probing as the 32-byte table



No false negatives, so a rejected key is absent; a false positive only costs a lookup that misses. Survivors are consumed in probe order with the probe counter set to their position: probes, relation and scalar are the pipeline's on every target.
