(a) 16 alternating same-target pairs, one binary, one pinned CPU (GitHub Actions ubuntu-24.04)

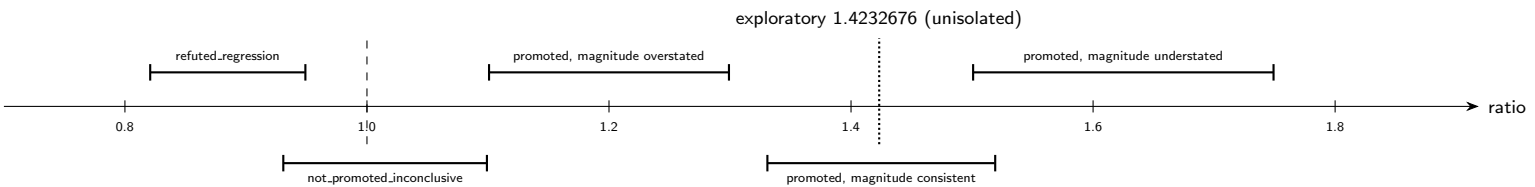

R = reference `packed_bucket22` (full 83-rotation scan); C = candidate `packed_bucket22_fastcanon` (longest-zero-gap scan); cap 180 s per arm

(b) One arm: what is timed (native `timing_ns`)

(c) Frozen decision rule on the paired bootstrap 95% interval of median(R/C) for the primary phase

Illustrative intervals only; no Tier 1 measurement exists yet. Any failed gate (preflight, throttling, OOM, RSS $>$ 1024 MiB, phase accounting, exact-field mismatch, fewer than 16 valid pairs) gives verdict `invalid` and leaves 1.42× exploratory.
